Global food production is suffering from an increasing number of “food shocks,” or sudden losses in food production, with most caused by extreme weather and geopolitical crises.

That is according to an international study led by researchers from the National Center for Ecological Analysis and Synthesis (NCEAS) at UC Santa Barbara, the Institute for Marine and Antarctic Studies (IMAS) and the Centre for Marine Socioecology at the University of Tasmania, who looked at the incidence of land and marine food shocks between 1961 and 2013.

Their findings, published in the journal Nature Sustainability, identified 226 food production shocks across 134 nations over the 53-year period, noting an increasing frequency of shocks across all sectors on a global scale.

The researchers looked at the full range of global food production systems, covering crops, livestock, fisheries and aquaculture.

“We were surprised to find that food shocks are increasing over time,” said co-author Ben Halpern, the director of NCEAS and a professor at UC Santa Barbara’s Bren School of Environmental Science & Management. “Global food supply is becoming increasingly variable and vulnerable.”

Lead author Richard Cottrell, a Ph.D. candidate at IMAS, said extreme weather was a major cause of shocks to crops and livestock, highlighting the vulnerability of food production to climate and weather volatility.
“In recent decades we have become increasingly familiar with images in the media of disasters such as drought and famine around the world,” said Cottrell. “Our study confirms that food production shocks have become more frequent, posing a growing danger to global food production.”

Cottrell said the increasing frequency of food shocks gave people and communities less recovery time between events and eroded their resilience.

“Reduced recovery time hinders coping strategies, such as accumulating food or assets for use during times of hardship,” he noted.

One key question addressed in the study was whether food shocks are less frequent in the ocean, where drought and other extreme weather events may be less common.

“We found that crops and livestock are slightly more shock-prone than fisheries and aquaculture,” said Cottrell, “and some regions, such as South Asia, are more frequently affected than others.”

Halpern added, “Although shocks are not yet as common for seafood, we were surprised to find that the shock rate in aquaculture has risen faster than any other food sector since the 1980s.”

The authors note that, combined with adverse climate conditions, conflict-related shocks to food production across sub-Saharan Africa and the Middle East have led to a rise in global hunger since 2010. Indeed, land-based crop and livestock production are particularly vulnerable to extreme weather events such as drought, which are expected to become more frequent and intense with climate change.

The authors found that overfishing, which is common around the world, was responsible for 45 percent of food shocks in fisheries, while disruptions to aquaculture production have risen faster and to a higher level than any other sector since the 1980s, in particular due to disease outbreaks.

“For the wealthy, food shocks may only be noticed as higher prices for certain food items in the grocery store,” noted Halpern. “But for the poor or impoverished, food shocks can keep people from being able to put food on their family’s table.”

“Globalized trade and the dependence of many countries on food imports mean that food shocks are a global problem, and the international community faces a
significant challenge to build resilience,” said Cottrell. “This can be done through measures such as investing in climate-smart food systems and building food reserves in import-dependent nations so they are better able to deal with the impact of disruptions caused by climate change.”

About UC Santa Barbara

The University of California, Santa Barbara is a leading research institution that also provides a comprehensive liberal arts learning experience. Our academic community of faculty, students, and staff is characterized by a culture of interdisciplinary collaboration that is responsive to the needs of our multicultural and global society. All of this takes place within a living and learning environment like no other, as we draw inspiration from the beauty and resources of our extraordinary location at the edge of the Pacific Ocean.
