## Studying Stability Under the Sea

An ecosystem arises from the effects of many different levels of organization. There are the species, their populations, the communities they live in, and the network of these communities over the entire region. But scientists are still exploring how the dynamics at different levels combine to determine the properties of the ecosystem as a whole.

Now a team led by UC Santa Barbara researchers has published a study detailing the factors at play in the understory of giant kelp forests in the Santa Barbara Channel. The results appear in the journal [Ecology](#).

“We wanted to understand which factors were most important in stabilizing the regional biomass of the macroalgae that thrive beneath the canopy of giant kelp,” said lead author [Thomas Lamy](#), a postdoctoral scholar at UC Santa Barbara’s Marine Science Institute (MSI). A stable community might see changes in its composition over time, but the overall mass of the plants and animals will remain relatively constant.

Scientists associate stability with two general characteristics: the diversity of different species and the number of patches in the region. If a region has many species, at least some will do well under a given set of conditions. Having a large number of independent communities can also promote stability. In this case, the health of each patch rises and falls independently, so they tend to average out, increasing the overall stability of the ecosystem.

Comparing an ecosystem to an investment portfolio, the stability provided by biodiversity would be like have a very diverse portfolio of companies. The spatial stability would be like investing over a large geographic region. Both aspects stabilize the system in different ways and to different extents.

Lamy and his colleagues were surprised to find a great deal of synchrony between the health of different patches of reef.

“I didn’t expect the spatial effects to be almost completely swamped out by the species effects,” said [Bob Miller](#), a research biologist with MSI and one of the papers’ coauthors. “Essentially, you’re getting more stability from having more species than you are from having more patches of reef where those species live.”

One possible explanation for this uniformity is that water tends to even out temperature differences, making variation negligible across a large area, in contrast with more variable conditions across terrestrial landscapes.

“Kelp forests along the California coast are made up of not only giant kelp, but of many other seaweed species that live beneath giant kelp,” said David Garrison, a program director in the National Science Foundation’s Division of Ocean Sciences, which funds the site where the research took place. “Kelp forests remain relatively stable because of the diversity and growth of these understory species. Understory biomass may be very important for the fish and invertebrates that live in kelp beds.”

A vibrant community thrives in the understory of the giant kelp forests in the Santa Barbara Channel.

This was one of the first studies to analyze the combined effects of different population levels on stability. “None of this was really done before,” Lamy said. “People would usually study two levels but never integrate all these levels together.”

But this perspective is crucial to develop an understanding of the ecosystem as a whole. “Natural ecosystems are like Russian dolls,” said Lamy. Stability at the regional scale is like the largest one: It’s what you see at first. But inside you can find the influence of individual species, multi-species communities, and meta-communities spanning the entire region.

The scope of the study was the result of two multi-year projects: the Santa Barbara Coastal Long Term Ecological Research project (LTER) and the Santa Barbara Channel Marine Biodiversity Observation Network (MBON). The [Santa Barbara Coastal LTER](#) is part of a nationwide network of similar, long term projects on a variety of ecosystems supported by the National Science Foundation. The Santa Barbara site focuses on studying the links between kelp forests, terrestrial and oceanic habitats. UC Santa Barbara’s Marine Science Institute has managed the project for nearly two decades.

The [Santa Barbara Channel MBON](#) is aimed at integrating current biodiversity data and exploring new, more effective ways to monitor biodiversity. It was a prototype project funded by NASA, the Bureau of Ocean Energy Management and NOAA and was designed to expand into a larger network. The MBON is in its fifth and final year, and the scientists involved are seeking funding to continue the project into the future.

“Studying these relationships is complicated, and you need a lot of data to do it,” said Miller. “We’re perfectly positioned here with the LTER to do studies like this — looking both at a fairly wide area and multiple species over time — all of which you have to do to understand stability.”

“The LTER network is critical in providing long term data and experiments that inform us about trends in marine ecosystems and how biodiversity can affect communities over time,” Miller added, “especially if you have extinctions and losses

taking place due to climate variability and other factors. The MBON has the potential to take this a giant step further to observe marine biodiversity across a much broader area, such as the entire west coast, using new technology. We're lucky here in Santa Barbara to have the LTER, but we need much more long-term biological data over huge areas if we want to really understand how our coastal oceans work and what their status is."

More research stories from the Santa Barbara Channel can be found in The Current's featured compilation, [Channel for Discovery](#).

## **About UC Santa Barbara**

The University of California, Santa Barbara is a leading research institution that also provides a comprehensive liberal arts learning experience. Our academic community of faculty, students, and staff is characterized by a culture of interdisciplinary collaboration that is responsive to the needs of our multicultural and global society. All of this takes place within a living and learning environment like no other, as we draw inspiration from the beauty and resources of our extraordinary location at the edge of the Pacific Ocean.
