Keeping California's oil in the ground will improve health but affect jobs

As society reckons with climate change, there's a growing call to keep fossil fuels right where they are, in the ground. But the impact of curtailing oil production will depend on the policies we implement to achieve this.

An interdisciplinary team of researchers investigated the carbon emissions, labor and health implications of several policies to reduce oil extraction, with a special focus on how the effects vary across different communities in California. Their results, published in *Nature Energy*, illustrate the tradeoffs between different strategies. For instance, models banning oil extraction near communities produced greater health benefits across the state, but they also led to more job losses, with disadvantaged communities feeling about one third of both the costs and the benefits.

With a goal to reach carbon neutrality by 2045, California is currently implementing some of the world's most ambitious climate policies. As the country's seventh largest oil-producing state and the world's fifth largest economy, California provides a unique setting to study supply-side decarbonization policies. It already has a carbon cap-and-trade program and is currently debating a setback policy that would ban new oil production near communities.

Many considerations

Petroleum production is a multifaceted endeavor. The greenhouse gas emissions from burning fossil fuels are the main driver of climate change. Extracting these resources also emits CO₂ into the environment, in addition to air pollution and toxic substances. Any policies seeking to curb oil production will affect people for better and worse. The industry employed 25,000 Californians in 2019, and provides tax revenue to local governments. “Our analysis is trying to quantify what those tradeoffs look like as the state considers different policies,” said co-author [Kyle Meng](#), an associate professor in UC Santa Barbara’s economics department and the Environmental Markets Lab (emLab) at the Bren School of Environmental Science & Management.

“We’re taking traditionally climate-focused policies and comparing them along local impacts, health benefits and employment costs,” added co-lead author [Paige Weber](#), an environmental economist at UNC Chapel Hill, previously an emLab post-doc.

The authors developed a framework to analyze the impact of three policies: an excise tax (paid per barrel); a carbon tax (paid per ton emitted); and setbacks at 1000 feet, 2500 feet and 1 mile. Taxes increase the cost of production, curbing activity and driving down emissions. Setbacks essentially ban extraction in areas where people live. In a [previous study](#), the authors found that production decreases because it might not be economical to drill somewhere else.

To compare between the policies, each setback distance had a corresponding excise and carbon tax level that achieved the same emissions target in 2045.

The authors started with a suite of models to predict oil production in California. Using historical data and economic theory, the team attempted to answer the following questions: Will they drill here? How much will a well produce? When will it shut down?

The researchers then modeled the health impacts of oil production emissions as they spread across California’s communities. Finally, they modeled the outcome that each policy would have on jobs and worker compensation. The authors were especially curious how these effects fell on people living in areas that meet California’s [definition](#) of a disadvantaged community.

They calibrated the health and labor consequences of each policy based on its ability to reduce carbon. “We ask, for the same greenhouse gas reduction, which policy has

greater health benefits and fewer labor costs, and how are these benefits and costs distributed?” Meng explained.

Always a tradeoff

Setbacks offered the greatest air-quality improvements, especially to disadvantaged communities. If you move oil production away from where people live, they’ll see health benefits. But there was a surprising tradeoff. When oil production is close to communities, so are the jobs it offers. “The same communities that benefit from cleaner air are also those facing labor market consequences,” Meng said.

During policy discussions, there’s often disagreement between groups highlighting the health impact of oil production and those focused on the employment benefits. “They’re often pitched as separate camps,” Meng continued. “But our analysis shows that costs and benefits can be borne by the same communities.”

Carbon and excise taxes both work by raising production costs, but the two policies target different oilfields. An excise tax eliminates the most expensive operations first, and falls roughly in the middle in terms of job and health implications.

“The cheapest way to reduce greenhouse gas emissions would be with a carbon tax because it goes after the most carbon-intensive oil extractors first,” Weber said. But since it takes the smallest number of wells out of production per ton of carbon emissions reduced, a carbon tax offers the lowest total health benefits, while also leading to the lowest job losses.

The authors believe their estimates of the health impacts are conservative. They focused solely on premature mortality, as other health impacts are more difficult to quantify. As a result, any action will likely improve the health of Californians more than what the study lays out.

Similarly, the researchers expect they overestimated the labor impacts because their framework doesn’t account for the possibility of re-employment. It assumes that every job lost results in unemployment.

The path forward

By 2045, California aims to reduce emissions in the transportation sector by 90% compared with 2019. And the Golden State is looking to many policies to achieve this.

“It’s a hotly debated issue right now because the governor just signed a law banning new oil drilling near communities,” said co-lead author [Ranjit Deshmukh](#), an assistant professor in UC Santa Barbara’s Environmental Studies Program. The oil industry quickly circumvented this action by collecting enough signatures to place a referendum on the next ballot.

“Unfortunately, even the largest setback distance did not reach the state’s greenhouse gas reduction target,” Weber said. “So, you’d need to combine a setback with another policy.”

The state currently has no plans to use an excise tax to reduce greenhouse gas emissions from oil extraction, the authors said. On the other hand, the state’s cap-and-trade program functions much like a carbon tax. The only difference is that the market finds a price based on the cap, rather than it being set by the government. That said, the cap-and-trade program spans many sectors in the state, not just fossil fuel extraction.

This paper captured employment and health impacts on a much finer resolution than previous studies. Looking at, say, county averages for health benefits can be misleading, the researchers explained. Consider Los Angeles county: There’s a lot of variation between people living in Compton and Hollywood, or Long Beach and Lancaster. “A much finer resolution analysis is needed to accurately answer the question of how different communities bear the costs or get the benefits of this oil phase-out,” Deshmukh said.

The empirical aspect of their framework was also an innovation. Most other studies used only engineering models to forecast production. Using detailed historical extraction data gave the authors more confidence in the accuracy of their projections.

The team has begun similar work investigating the health and labor impacts of phasing out oil refining in California. And they plan to extend their analysis on petroleum production to the rest of the country. They hope their work will guide policymakers towards an effective, equitable solution for curbing fossil fuel extraction. One that maximizes its benefits while reducing its drawbacks.

About UC Santa Barbara

The University of California, Santa Barbara is a leading research institution that also provides a comprehensive liberal arts learning experience. Our academic community of faculty, students, and staff is characterized by a culture of interdisciplinary collaboration that is responsive to the needs of our multicultural and global society. All of this takes place within a living and learning environment like no other, as we draw inspiration from the beauty and resources of our extraordinary location at the edge of the Pacific Ocean.
